**METHODOLOGY**

The NBC News|SurveyMonkey Alabama State Poll was conducted online among a sample of 1,498 adults aged 18 and over who live in Alabama from March 12 through March 25, 2018. Respondents for this survey were selected from the nearly three million people who take surveys on the SurveyMonkey platform each day.

A raking was employed to construct state-level weights. First, postal zip codes are classified into five groups according to their population sizes. Initial respondent weights are derived from estimated sampling rates on the SurveyMonkey News Tracking Endpage within each zip code group. The initial respondent weights are then raked by gender, age, race, and education within the state to match targets obtained from the American Community Survey.

Because the sample is based on those who initially self-selected for participation rather than a probability sample, no estimates of sampling error can be calculated. All surveys may be subject to multiple sources of error, including, but not limited to sampling error, coverage error, and measurement error.

To assess the variability in the estimates and account for design effects, we create a bootstrap confidence interval to produce an error estimate. The bootstrap confidence interval for this survey is plus or minus 4.5 percentage points.

To calculate the bootstrap confidence interval, we use the weighted data to generate 10,000 independent samples and calculate the 95% confidence intervals for the weighted average. When analyzing the survey results and their accuracy, this error estimate should be taken into consideration in much the same way that analysis of probability polls takes into account the margin of sampling error.

**METHODOLOGY**

The NBC News|SurveyMonkey Tennessee State Poll was conducted online among a sample of 1,710 adults aged 18 and over who live in Tennessee from March 12 through March 25, 2018. Respondents for this survey were selected from the nearly three million people who take surveys on the SurveyMonkey platform each day.

A raking was employed to construct state-level weights. First, postal zip codes are classified into five groups according to their population sizes. Initial respondent weights are derived from estimated sampling rates on the SurveyMonkey News Tracking Endpage within each zip code group. The initial respondent weights are then raked by gender, age, race, and education within the state to match targets obtained from the American Community Survey.

Because the sample is based on those who initially self-selected for participation rather than a probability sample, no estimates of sampling error can be calculated. All surveys may be subject to multiple sources of error, including, but not limited to sampling error, coverage error, and measurement error.

To assess the variability in the estimates and account for design effects, we create a bootstrap confidence interval to produce an error estimate. The bootstrap confidence interval for this survey is plus or minus 4.1 percentage points.

To calculate the bootstrap confidence interval, we use the weighted data to generate 10,000 independent samples and calculate the 95% confidence intervals for the weighted average. When analyzing the survey results and their accuracy, this error estimate should be taken into consideration in much the same way that analysis of probability polls takes into account the margin of sampling error.

A multi-stage raking was employed to construct region-level weights. First state-division geographic units are defined according to state population sizes and Census division classification within the sampled region. States with over five million residents are defined as stand-alone units, while smaller states are grouped together within a Census division to form secondary geographic units. Then postal zip codes are classified into five groups according to their population sizes within each geographic unit. Initial respondent weights are derived from estimated sampling rates on the SurveyMonkey News Tracking Endpage within each zip code group. At first-stage of raking, the initial weights are controlled to geographic unit population sizes. The second-stage raking adjusts first-stage weights by gender, age, race, and education to match targets obtained from the American Community Survey within the geographic unit.
